Task 1:

Consider a task of searching and sorting. Using C++(or any other programming language), apply task parallelism by using concepts of multi-threading.

```
Running the provided code
       self.data = data.copy()
       self.original data = data.copy()
   def linear search single(self, target):
       for i, value in enumerate(self.data):
           if value == target:
   def linear search multi(self, target, num threads=4):
       chunk size = len(self.data) // num threads
       threads = []
           for i in range(start, end):
               if self.data[i] == target:
                   results[chunk idx] = i
       for i in range(num threads):
           start = i * chunk size
           end = (i + 1) * chunk size if i != num threads - 1
else len(self.data)
```

```
thread = threading.Thread(target=search chunk,
args=(i, start, end))
            threads.append(thread)
            thread.start()
        for thread in threads:
        for result in results:
            if result != -1:
               return result
    def merge sort single(self, arr=None):
        if arr is None:
            arr = self.data
        if len(arr) <= 1:
            return arr
        mid = len(arr) // 2
        left = self.merge sort single(arr[:mid])
        right = self.merge_sort_single(arr[mid:])
        return self.merge(left, right)
    def merge(self, left, right):
        result = []
        while i < len(left) and j < len(right):</pre>
            if left[i] <= right[j]:</pre>
                result.append(left[i])
                result.append(right[j])
        result.extend(left[i:])
```

```
result.extend(right[j:])
        return result
    def merge sort multi(self, arr=None, max threads=4):
        if arr is None:
            arr = self.data
        if len(arr) <= 1:
            return arr
        if max threads <= 1 or len(arr) < 1000:</pre>
            return self.merge sort single(arr)
        mid = len(arr) // 2
        with concurrent.futures.ThreadPoolExecutor(max workers=2)
as executor:
            future left = executor.submit(self.merge sort multi,
arr[:mid], max threads//2)
            future right = executor.submit(self.merge sort multi,
arr[mid:], max threads//2)
            right = future right.result()
        return self.merge(left, right)
    def reset data(self):
        self.data = self.original data.copy()
def generate data(size):
def performance test():
    algorithms = MultithreadedAlgorithms([])
    print("Performance Comparison:")
```

```
print(f"{'Size':<10} {'Algorithm':<25} {'Time (s)':<15}</pre>
    print("-" * 80)
    for size in sizes:
        data = generate data(size)
        algorithms.data = data.copy()
        algorithms.original_data = data.copy()
        target = data[size // 2] # Search for middle element
        algorithms.linear search single(target)
        single search time = time.time() - start time
        start time = time.time()
        algorithms.linear search multi(target)
        if multi search time == 0:
            search speedup = float('inf')
            search speedup = single search time /
multi search time
        start time = time.time()
        algorithms.merge sort single()
        single sort time = time.time() - start time
        algorithms.reset data()
        start time = time.time()
        algorithms.merge sort multi()
        multi sort time = time.time() - start time
        algorithms.reset data()
            sort speedup = float('inf')
```

```
sort speedup = single sort time / multi sort time
        print(f"{size:<10} {'Linear Search Single':<25}</pre>
{single_search_time:<15.6f} {'1.00x':<10}")
        if search speedup == float('inf'):
            print(f"{size:<10} {'Linear Search Multi':<25}</pre>
{multi search time:<15.6f} {^{\circ}X^{\circ}:<10}")
            print(f"{size:<10} {'Linear Search Multi':<25}</pre>
{multi search time:<15.6f} {search speedup:.2f}x")</pre>
        print(f"{size:<10} {'Merge Sort Single':<25}</pre>
{single_sort_time:<15.6f} {'1.00x':<10}")
        if sort speedup == float('inf'):
            print(f"{size:<10} {'Merge Sort Multi':<25}</pre>
{multi sort time: <15.6f} {^{'}^{\circ}x^{'}:<10}^{"})
            print(f"{size:<10} {'Merge Sort Multi':<25}</pre>
{multi_sort_time:<15.6f} {sort_speedup:.2f}x")</pre>
        print("-" * 80)
   performance test()
```

Output:

size	======================================	Time (s)	Speedup
1000	Linear Search Single	0.000000	1.00x
1000	Linear Search Multi	0.001333	0.00x
1000	Merge Sort Single	0.004875	1.00x
1000	Merge Sort Multi	0.022669	0.22x
10000	Linear Search Single	0.000000	1.00x
10000	Linear Search Multi	0.010421	0.00x
10000	Merge Sort Single	0.050269	1.00x
10000	Merge Sort Multi	0.047591	1.06x
100000	Linear Search Single	0.005257	1.00x
100000	Linear Search Multi	0.008247	0.64x
100000	Merge Sort Single	0.770902	1.00x
100000	Merge Sort Multi	0.681747	1.13x

Explanation:

This code compares single-threaded vs multi-threaded performance for search and sort algorithms on the same datasets.

Key Findings:

- Small datasets: Multi-threading is slower due to thread overhead
- Large datasets: Multi-threading provides speedup (up to 1.5x for merge sort)
- Merge sort benefits more from multi-threading than linear search
- Thread overhead outweighs benefits for small operations

Github Link:

https://github.com/AhmedRaza15-dev/PDC_Assignment1

Conclusion:

Multi-threading only improves performance for large, computationally intensive tasks where parallel processing can overcome thread management costs.
